

Preregistered selectivity prediction: not supported, and internally inconsistent

Procrustes selectivity
(predicted: c2b helped more than b2c)

+0.02 threshold

CORAL selectivity
(predicted: b2c helped more than c2b)

+0.02 threshold

95% CI, 1,000-rep bootstrap over the 80 held-out payload blocks (paired per cell). Red segments = CI entirely below zero (significant in the WRONG direction). Mean interaction: Procrustes +0.009, CORAL +0.002 — both far below the predeclared +0.02 practical-rescue threshold. Procrustes: 5/9 cells significant in the predicted direction but 2/9 significant in the WRONG direction; per-model averages disagree in sign. CORAL: only 3/9 cells significant in the predicted direction versus 4/9 significant in the WRONG direction — more cells contradict the prediction than support it. Neither hypothesis is supported. Signal/noise decomposition remains the endpoint.
